Paradigms for Designing Algorithms

Greedy algorithm

- Make a greedy choice
- Prove that the greedy choice is safe
- Reduce the problem to a sub-problem and solve it iteratively
- Usually for optimization problems

Divide-and-conquer

- Break a problem into many independent sub-problems
- Solve each sub-problem separately
- Combine solutions for sub-problems to form a solution for the original one
- Usually used to design more efficient algorithms

Paradigms for Designing Algorithms

Dynamic Programming

- Break up a problem into many overlapping sub-problems
- Build solutions for larger and larger sub-problems
- Use a table to store solutions for sub-problems for reuse

Recall: Computing the *n*-th Fibonacci Number

- $F_0 = 0, F_1 = 1$
- $F_n = F_{n-1} + F_{n-2}, \forall n > 2$
- $\bullet \ \, \text{Fibonacci sequence:} \ \, 0,1,1,2,3,5,8,13,21,34,55,89,\cdots \\$

$\mathsf{Fib}(n)$

- 1: $F[0] \leftarrow 0$
- 2: $F[1] \leftarrow 1$
- 3: **for** $i \leftarrow 2$ to n **do**
- 4: $F[i] \leftarrow F[i-1] + F[i-2]$
- 5: **return** F[n]

Recall: Interval Schduling

Input: n jobs, job i with start time s_i and finish time f_i

i and j are compatible if $\left[s_i,f_i\right)$ and $\left[s_j,f_j\right)$ are disjoint

Output: a maximum-size subset of mutually compatible jobs

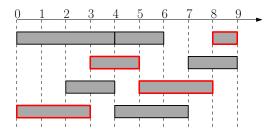

Recall: Interval Schduling

Input: n jobs, job i with start time s_i and finish time f_i

i and j are compatible if $\left[s_i,f_i\right)$ and $\left[s_j,f_j\right)$ are disjoint

Output: a maximum-size subset of mutually compatible jobs

Weighted Interval Scheduling

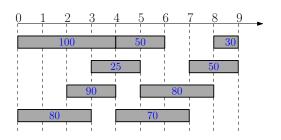

Input: n jobs, job i with start time s_i and finish time f_i each job has a weight (or value) $v_i > 0$ i and j are compatible if $[s_i, f_i)$ and $[s_j, f_j)$ are disjoint

Output: a maximum-weight subset of mutually compatible jobs

Weighted Interval Scheduling

Input: n jobs, job i with start time s_i and finish time f_i each job has a weight (or value) $v_i > 0$

i and j are compatible if $[s_i, f_i)$ and $[s_j, f_j)$ are disjoint **Output:** a maximum-weight subset of mutually compatible jobs

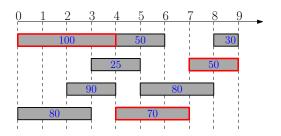

Weighted Interval Scheduling

Input: n jobs, job i with start time s_i and finish time f_i each job has a weight (or value) $v_i > 0$

i and j are compatible if $\left[s_{i},f_{i}\right)$ and $\left[s_{j},f_{j}\right)$ are disjoint

Output: a maximum-weight subset of mutually compatible jobs

Optimum value = 220

Input: an integer bound W > 0

a set of n items, each with an integer weight $w_i > 0$

Output: a subset S of items that

$$\text{maximizes } \sum_{i \in S} w_i \qquad \text{ s.t. } \sum_{i \in S} w_i \leq W.$$

Input: an integer bound W > 0

a set of n items, each with an integer weight $w_i > 0$

Output: a subset S of items that

$$\text{maximizes } \sum_{i \in S} w_i \qquad \text{s.t.} \sum_{i \in S} w_i \leq W.$$

 Motivation: you have budget W, and want to buy a subset of items, so as to spend as much money as possible.

Output: a subset S of items that

ullet Motivation: you have budget W, and want to buy a subset of items, so as to spend as much money as possible.

Example:

•
$$W = 35, n = 5, w = (14, 9, 17, 10, 13)$$

Input: an integer bound W > 0

a set of n items, each with an integer weight $w_i > 0$

Output: a subset S of items that

ullet Motivation: you have budget W, and want to buy a subset of items, so as to spend as much money as possible.

Example:

- W = 35, n = 5, w = (14, 9, 17, 10, 13)
- Optimum: $S = \{1, 2, 4\}$ and 14 + 9 + 10 = 33

Candidate Algorithm:

- Sort according to non-increasing order of weights
- \bullet Select items in the order as long as the total weight remains below ${\cal W}$

- Summary

Dynamic Programming

- Break up a problem into many overlapping sub-problems
- Build solutions for larger and larger sub-problems
- Use a table to store solutions for sub-problems for reuse

Comparison with greedy algorithms

- Greedy algorithm: each step is making a small progress towards constructing the solution
- Dynamic programming: the whole solution is constructed in the last step

Comparison with divide and conquer

- Divide and conquer: an instance is broken into many independent sub-instances, which are solved separately.
- Dynamic programming: the sub-instances we constructed are overlapping.

Definition of Cells for Problems We Learnt

- \bullet Weighted interval scheduling: $opt[i] = \mbox{value of instance defined}$ by jobs $\{1,2,\cdots,i\}$
- \bullet Subset sum, knapsack: opt[i,W']= value of instance with items $\{1,2,\cdots,i\}$ and budget W'
- ullet Longest common subsequence: $opt[i,j] = \mbox{value of instance}$ defined by A[1..i] and B[1..j]
- ullet Shortest paths in DAG: f[v] = length of shortest path from s to v
- ullet Matrix chain multiplication, optimum binary search tree: $opt[i,j] = \mbox{value of instances defined by matrices } i \mbox{ to } j$
